The McCormac 7th edition emphasizes the importance of proper reinforcement detailing and concrete quality to optimize this interaction.

Load Considerations Design begins with assessing the various loads the structure will encounter, including:

- Dead loads (self-weight of the structure and permanent fixtures)
- Live loads (occupant loads, furniture, transient forces)
- Environmental loads (wind, snow, temperature variations)
- Seismic loads (earthquake forces)

The code mandates specific factors and load combinations to account for uncertainties and to ensure safety margins.

Design Methodology According to McCormac 7th
Limit State Design Approach The McCormac 7th adheres to the limit state design philosophy, which ensures that structures:

- Maintain safety against collapse

(Ultimate Limit State) Provide acceptable performance during service (Serviceability Limit State) This approach involves using load factors and resistance factors to account for uncertainties in load estimation and material strengths.

Step-by-Step Design Procedure

Determine Loads and Load Combinations: Using applicable factors, calculate factored loads based on the code's prescribed combinations.

Select Structural System and Materials: Decide on the type of reinforced concrete member (beam, slab, column) and specify concrete strength and reinforcement grade.

Calculate Required Cross-Sectional Areas: Based on bending moments, shear forces, and axial loads, determine the necessary reinforcement using formulas provided in the code.

Check Serviceability Limits: Verify deflections, crack widths, and other serviceability criteria to ensure comfort and durability.

Detail Reinforcement: Follow detailing rules for anchorage, spacing, and cover to ensure proper performance and compliance.

Perform Structural Analysis: Use methods such as moment distribution, finite element analysis, or simplified approaches, as appropriate.

Key Design Principles and Formulas

Flexural Design

Ultimate Moment Capacity (M_u): Calculated based on the balanced reinforcement ratio, concrete strength, and reinforcement steel yield strength.

Reinforcement Area (A_{st}): Derived from the formula: $A_{st} = (M_u) / (\phi f_y (d - a/2))$ where ϕ is the strength reduction factor, f_y is steel yield strength, d is effective depth, and a is the depth of the equivalent rectangular stress block.

Limitations: The code provides formulas for minimum and maximum reinforcement ratios to prevent brittle failure or under-reinforced sections.

Shear Design

Shear Strength (V_c): Calculated based on concrete properties: $V_c = 0.6 \phi f_c b d$

Shear Reinforcement: When shear forces exceed V_c , shear stirrups or ties are required, with spacing and size governed by the code.

Axial Load and Combined Bending and Axial Forces

The interaction between axial loads and bending moments is addressed through interaction diagrams and formulas, ensuring the combined effects do not compromise structural integrity.

Serviceability and Durability Considerations

Crack Control and Deflection

The code prescribes maximum crack widths for different exposure conditions, influencing reinforcement detailing. Deflection limits are specified to prevent excessive bending or vibration, with calculations based on stiffness and loading.
